

How to install Eclipse Simplest way (CEEROOT)

(Method 2 - recommended -) cmake does the job for you

- Important: Your folder to build CEEROOT into must not be in the trunk/source code tree! Place it for example in the mother directory. Additionally link the source folder into the build folder.
- >/home/shyam/GSI (All files are here main directory includes FAIR and CEE)
- >/home/shyam/GSI/CeeRoot/build
- > ln -s ../ ./CeeRoot (This will create a soft link of GSI in build directory for code browsing)
- > cmake ../
- > make
- > cmake ../ -G 'Eclipse CDT4 - Unix Makefiles'
- Import now this project into eclipse:
- File > Import
- Select "General > Existing Projects into Workspace" and press "Next"
- "Browse" the root directory of your build and confirm
- Do NOT select "Copy projects into workspace"
- Confirm everything and your project tree should contain the build folder as well as the source tree
- This will not do the indexing of the macro: For the macro you can do file → open, then you can open it if you want to see the class right click and open declaration.
- Done !!!
